

12. WSN Security II.

Specific attacks on WSN, protection

Wireless sensor networks

Martin Úbl

2023/24

Security

Initial remarks

- ❑ when considering WSN security, there are lots of possible views
- ❑ important remark: protecting everything with maximum security costs a fortune!
- ❑ goal: balance costs and reasonable protection and security
- ❑ important remark: if the attacker truly wants to compromise our network, he will eventually find a way
- ❑ goal: make it cost him more than us (ideally)

Security

Initial remarks

- ☐ an attack is possible on all layers
- ☐ it depends on what is the goal of the attacker
 - ☐ take down our network?
 - ☐ inject a node?
 - ☐ fail the mission by poisoning data?
 - ☐ deplete our batteries?
 - ☐ raise false alarms?

Security

Initial remarks

- ❑ many types of attacks
 - ❑ denial of service (DoS) – reduce availability or shut down the network
 - ❑ depletion attack – attempt to deplete battery quickly
 - ❑ injection attack – injecting fake data
 - ❑ redirection attack – redirect traffic (L2, L3, ...)
 - ❑ spoofing attack – attempt to spoof node info and impersonate one
 - ❑ congestion attack – imitation of traffic, nodes sense carrier wave and do not transmit
 - ❑ man in the middle attack (MitM) – transparently spoofing both sides of communication
 - ❑ side-channel attack – extract information from other than a primary source (e.g., timing attack, ...)
 - ❑ etc.

Security

Physical layer

- ❑ **attacks on physical layer**
- ❑ *jamming*
 - ❑ transmitting garbage data on our channel
 - ❑ a type of DoS attack
 - ❑ protection: spread spectrum techniques
 - ❑ DSSS – a slightly more resistant against jamming
 - ❑ FHSS – frequency hopping requires the attacker to jam more frequencies
 - ❑ rapid-hopping FHSS – jam all the frequencies

Security

Physical layer

- ❑ *tampering*
 - ❑ stealing the node to deconstruct it, reverse engineer it, or scan its memory
 - ❑ can be dangerous – reading the memory directly may reveal encryption keys
 - ❑ protection:
 - ❑ physical node security – encasement, anchoring
 - ❑ encasement with self-destruction tampering protection
 - ❑ – when someone tries to steal the node, sensor detects it and performs self-destruction
 - ❑ detonates a small charge
 - ❑ or erases the memory

Security

Physical layer

☐ *on-site node scan*

- ☐ do not steal the node, but attempt to read the memory/analyze it on-site
- ☐ for example – read the crypto keys from external memory
- ☐ protection:
 - ☐ physical node security – encasement, anchoring
 - ☐ encrypted external flash memory
 - ☐ short-lived keys

Security

Data link layer

- ❑ **attacks on data link layer**
- ❑ *fake preamble injection* (asynchronous TDMA)
 - ❑ depletion attack
 - ❑ attacker injects fake preambles to wake up nodes
 - ❑ protection:
 - ❑ do not use asynchronous TDMA
 - ❑ pseudo-random information in preables
 - ❑ frequency hopping or FDMA in general – additional form of security to make it harder

Security

Data link layer

- ❑ *targetted slot attack* (synchronous TDMA)
 - ❑ specific attack on a specific protocol
 - ❑ in general, synchronous TDMA are hard to exploit without any prior knowledge about their implementation
 - ❑ but if somebody manages to extract that info from the binary code of stolen node, there is a chance
 - ❑ protection:
 - ❑ allow MAC protocol reconfiguration
 - ❑ dynamic MAC protocols
 - ❑ dynamic slot allocations

Security

Data link layer

☐ *spoofing attack*

- ☐ attacker injects a node, that tries to spoof another node
- ☐ it uses its address (HW address), frequency band and other characteristics
- ☐ protection:
 - ☐ authentication on L2, Message Authentication Code
 - ☐ duplicate detection (if the attacker did not shut down the other node)
 - ☐ upper layer authentication methods

Security

Data link layer

- ❑ *Sybil attack* – a variant of spoofing attack
 - ❑ to introduce an element of confusion, the attacker tries to spoof different nodes at different times
 - ❑ this will probably seem like an error to the programmer
 - ❑ the attacker may proceed with another attacks, since he distracted the administrators
 - ❑ protection:
 - ❑ same as the spoofing attacks
 - ❑ it is just important to know about this type of attack

Security

Data link layer

☐ *Hello attack*

- ☐ advertising L2 hello packets to create false neighborhoods
- ☐ form of a redirection attack
- ☐ protection:
 - ☐ authentication on L2 (MAC-based auth)
 - ☐ handshake procedure instead of a simple hello frame (with a form of authentication)

Security

Network layer

- ❑ **attacks on network layer**

- ❑ *sinkhole attack*

- ❑ an attacker injects a node, that merely routes the data
- ❑ other nodes stores the advertised path and start to use it
- ❑ the attacker now legitimately routes part of the data
- ❑ protection:
 - ❑ L3 encryption (to avoid using injected nodes for relaying data)
 - ❑ diverting part of data through a redundant path
 - ❑ lower layer node injection protection

Security

Network layer

- ❑ *wormhole attack*
 - ❑ a variant of sinkhole attack, that advertises a very efficient network route to the data sink
 - ❑ nodes start to use the route
 - ❑ attacker now legitimately routes all the data from this part of network
 - ❑ protection:
 - ❑ message authentication codes on routing info
 - ❑ L3 encryption
 - ❑ redundant paths
 - ❑ lower layer node injection protection

Security

Network layer

☐ *flooding attack*

- ☐ forces nodes to route injected data (conforming to protocol)
- ☐ form of a DoS attack
- ☐ protection:
 - ☐ L3 encryption
 - ☐ flooding node detection
 - ☐ lower layer node injection protection

Security

Network layer

- ☐ *spoofing attack* or *Sybil attack*
- ☐ practically the same implications, as on L2
- ☐ additionally, we may protect implicitly by using lower layer security mechanisms

Security

Network layer

- ❑ *black hole attack*
 - ❑ always in combination with spoofing, wormhole or sinkhole attacks
 - ❑ the injected node drops all the packets
 - ❑ form of a DoS attack
- ❑ *grey hole attack*
 - ❑ as above, but drops just a part of packets
 - ❑ this also introduces a confusion element and distracts the administrators

Security

Transport layer

attacks on transport layer

acknowledge attack

- ☐ injecting false acknowledge packets
- ☐ may induce congestion, if we aim for higher data rates
- ☐ may acknowledge data, that were lost on its way
- ☐ potentially combined with black/grey hole attacks – the attacker drops the L3 packet, but acknowledges it on L4
- ☐ protection:
 - ☐ lower layer node injection protection
 - ☐ ACKs may contain checksums of acknowledged data
 - ☐ authentication on L4 for ACKs
 - ☐ redundant ACKs for groups of data, e.g., 4 segments, 4 partial ACKs and 1 "whole data ACK"

Security

Transport layer

- ❑ *congestion attack*
 - ❑ attacker injects packets to induce congestion
 - ❑ not necessarily at the rate to induce a real congestion
 - ❑ e.g., if using the sliding window approach (rarely in WSN), attempt to inject false congestion detection segments
 - ❑ protection:
 - ❑ lower layer node injection protection
 - ❑ authentication on L4 for control overhead segments
 - ❑ distributed congestion detection (not end-to-end)

Security

Transport layer

- ❑ *connection flood attack*
 - ❑ if using a stateful approach, the attacker may create a fake connection attempts
 - ❑ this floods the node connection table with fake info
 - ❑ results in node DoS
 - ❑ protection:
 - ❑ ideally do not use stateful L4 approach in WSNs
 - ❑ authentication during state establishment
 - ❑ state information timeout

Security

Transport layer

☐ *NACK attack*

- ☐ injecting fake NACK messages to force retransmission
- ☐ may be seen as a depletion attack
- ☐ protection:
 - ☐ authentication for acknowledgments
 - ☐ do not use NACK-based protocol
 - ☐ do not use reliable protocol at all, if it is not really required

Security

Transport layer

- ❑ *desynchronization attack*
 - ❑ inject a fake data to alter state information
 - ❑ e.g., inject segments which imitates next part of data, so the target node is forced to acknowledge it
 - ❑ this triggers a resynchronization of both nodes, because sequence numbers no longer match
 - ❑ protection:
 - ❑ authentication
 - ❑ checksums for acknowledged data
 - ❑ fixed segment sizes

Security

Application layer

- ❑ **attacks on application layer**
- ❑ *time synchronization attack*
 - ❑ attacker attempts to inject fake time source
 - ❑ this potentially desynchronizes all nodes
 - ❑ all nodes lose synchronization → no communication (if using e.g., synchronous TDMA)
 - ❑ protection:
 - ❑ authentication of time sources (carefully – crypto actions induce additional delays)
 - ❑ require multiple time sources
 - ❑ lower layer node injection protection (may not work as the time source may be implicitly an external node)

Security

Application layer

- ❑ *localization attack*
 - ❑ injecting fake location info
 - ❑ e.g., the attacker imitates the anchor node
 - ❑ since anchor nodes may be implicitly external nodes, this might be possible
 - ❑ protection:
 - ❑ authentication of external nodes (also carefully – some localization methods require precise timing)
 - ❑ require more location sources, detect outliers

Security

Application layer

- ❑ *protocol-specific attacks*
- ❑ some attacks may be targetted to a specific application protocol used
- ❑ MQTT – publish flooding
 - ❑ MQTT supports authentication and authorization – use it
- ❑ CoAP – query flooding
 - ❑ pretty much the same
- ❑ lots of attacks can be avoided by using encryption or authentication

Security

Final remarks

- ❑ it's not about implementing all protection mechanisms
 - ❑ that would take a long time
 - ❑ consume too much memory
 - ❑ consume too much computational time
 - ❑ eventually, we will "shoot ourselves in foot", because our security measurements will consume too much energy
- ❑ depending on application, choose the most important ones
- ❑ implement the most important mechanisms

Security

Final remarks

- ❑ use proven techniques
- ❑ "security by obscurity" is a very dangerous paradigm in low-power applications
 - ❑ obscurity usually indicates additional work
 - ❑ energy consuming

Security

Final remarks

- ❑ the first thing somebody usually tries – L1 attacks
 - ❑ steal a node
 - ❑ jam the frequency
 - ❑ read the memory
 - ❑ destroy network sink
 - ❑ etc.
- ❑ do not confuse mistake with intent

Security

Final remarks

- ❑ use encryption and authentication
 - ❑ at least on some layers
- ❑ if your network supports firmware updates, OAD or dynamic retasking, always use digital signatures
 - ❑ exploiting this procedure may lead to taking over the whole network

Security

Final remarks

- ❑ use advanced encryption and security on all nodes outside WSN
 - ❑ edge and cloud nodes should use the highest possible protection
- ❑ there is much higher probability, that somebody attempts to compromise your server in the Internet, than your WSN
- ❑ if your server can control the WSN, taking over the server means taking over the WSN
